

# UNIVERSITI TUN HUSSEIN ONN MALAYSIA

# FINAL EXAMINATION SEMESTER I SESSION 2019/2020

**COURSE NAME** 

**GEOTECHNICS 2** 

COURSE CODE

BFC34402

PROGRAMME CODE :

**BFF** 

EXAMINATION DATE :

DECEMBER 2019 / JANUARY 2020

**DURATION** 

2 HOURS 30 MINUTES

**INSTRUCTIONS** 

ANSWER ALL QUESTIONS IN

PART A. ANSWER ANY TWO (2)

QUESTIONS IN PART B.

THIS QUESTION PAPER CONSISTS OF NINE (9) PAGES

# CONFIDENTIAL

#### BFC34402

## PART A: ANSWER ALL QUESTIONS

Q1 (a) (i) Natural slopes which were stable for many years may suddenly fail due to some causes. The Varnes system divides slope failures into five types. Briefly explain all **FIVE (5)** types of slope failures with relevant sketch.

(10 marks)

(ii) Based on the answer in Q1(a)(i), discuss TWO (2) similarities among these modes of slope failure.

(4 marks)

(iii) Define the term safety factor of slope stability and briefly explain the effect of rainfall on the stability of slope.

(5 marks)

(b) Briefly explain the importance of distiguishing flow failures and slip failures.

(6 marks)

- (c) An embankment 15 m high is subjected periodically to full submergence and drawdown conditions. Given that the slope angle, specific gravity, void ratio and friction angle are 45°, 2.75, 0.9 and 20°, respectively.
  - (i) Determine the cohesion of soil, c<sub>u</sub> required to give a factor of safety 1.5 in the submerged condition. Use Taylor's stability number curves in **Figure Q1(c)** in this case.

(5 marks)

(ii) Determine the cohesion of soil, c' required to give a factor of safety 1.3 in the drawdown condition. Use Taylor's stability number curves in **Figure Q1(c)** in this case.

(5 marks)

(iii) Discuss the effects of sudden drawdown on the stability of slope.

(5 marks)

# PART B: ANSWER TWO (2) QUESTIONS ONLY

Q2 (a) Briefly explain FIVE (5) constraints for sketching flow net.

(5 marks)

(b) Sultan Mahmud Dam, located in Tasik Kenyir, Terengganu, contained with levees. Levee #111 runs North-South about 2 kilometres west of Kuala Berang and its cross section is shown in **Figure Q2(b)**. Laboratory tests indicate that the permeability of the 80-year old levee is 0.30 m/day. Calculate the volume of water lost through the levee along each kilometer in m³/day.

(5 marks)

- (c) A dam shown in **Figure Q2** (c) retains 6m of water. A sheet pile wall on the upstream side (which is to reduce seepage under the dam) penetrates 4m into 10m thick silty sand stratum. Below the silty sand is a thick deposit of clay. Assume that the silty sand is homogeneous and isotropic.
  - (i) Calculate q in cm/s.

(2 marks)

(ii) Calculate the pore water pressure distribution on the front of the sheet pile (at every 2m @ at point A, F and G). Given the  $N_d$  of point A, F and G are 0.5, 1.5 and 3.0 respectively.

(5 marks)

(iii) Calculate the pore water pressure distribution at the base of the dam. (at every 5m @ at point A, B, C, D and E). Given the  $N_d$  of point A, B, C, D and E are 5.6, 6.7, 8.0, 10.0, 13.0 respectively.

(8 marks)

(iv) Determine the uplift force.

(2 marks)

(v) Determine maximum hydraulic gradient given that L<sub>min</sub> is 0.85m.

(1 mark)

(vi) Determine Factor of Safety. Identify either piping will occur or not.

(2 marks)

Q3 (a) Define the terms of coefficient of lateral earth pressure at rest and coefficient of active lateral earth pressure.

(4 marks)

(b) Briefly explain **TWO** (2) differences in assumptions between Rankine earth pressure theory and Coulomb earth pressure theory.

(6 marks)

- (c) For the frictionless wall shown in Figure Q3(c), determine the following;
  - (i) The active lateral earth pressure coefficients.

(2 marks)

(ii) The active lateral earth pressure distributions.

(8 marks)

(iii) The active resultant lateral forces.

(6 marks)

(iv) The location of active resultant lateral forces.

(4 marks)

Q4 (a) In general, the soil settlement caused by loads may be divided into THREE (3) broad stages. Explain each stage with the aid of sketches/ diagrams.

(8 marks)

- (b) A 2m clay layer underlies a layer of sand layer of 4m depth as shown in **Figure Q4(b)**. The groundwater level was observed to be very deep. The unit weight of the sand layer is 17kN/m<sup>3</sup> while the clay layer is 19kN/m<sup>3</sup>. The structure load will develop stress at 100kPa. It was observed that in place void ratio is 0.73. The collected data from the laboratory consolidation test are shown in **Table Q4(b)**.
  - (i) Make necessary calculations and draw an e versus  $log \sigma$  curve based on given data in **Table Q4(b)**. Given dry mass of specimen = 100g, height of specimen at the beginning of the test = 20mm, specific gravity = 2.7 and specimen surface area = 32 cm<sup>2</sup>.

(10 marks)

(ii) Determine compression index and swell index.

(4 marks)

(iii) Determine the settlement of the clay layer caused by primary consolidation if the clay is over consolidated.

(4 marks)

(iv) Calculate the settlement of the clay layer caused by primary consolidation if the clay is normally consolidated and the groundwater level was located at the middle of the sand layer. Given the saturated unit weight of the sand layer is 18 kN/m³ while the clay layer is 19.5kN/m³.

(4 marks)
